MINI PROJECT REPORT

REGISTER NUMBER	2117240070049
NAME	G Deepak
PROJECT TITLE	Gold Price Prediction using Linear Regression
DATE OF SUBMISSION	
FACULTY IN-CHARGE	**Mrs. M. Divya**

Signature of Faculty In-charge **Signature of HoD**

Internal Examiner **External Examiner**

INTRODUCTION

Gold is one of the most valuable commodities globally and is widely used as an investment asset. Predicting gold prices is crucial for investors, traders, and financial analysts to make informed decisions.

Machine Learning (ML) provides powerful tools to analyze historical data and predict future trends. In this project, the **Linear Regression algorithm** is used to predict gold prices based on historical price data and engineered features such as lag values and rolling statistics.

Linear Regression is a supervised learning algorithm used for predicting continuous values. It establishes a linear relationship between independent variables (features) and a dependent variable (target).

This project aims to:

- Analyze historical gold price trends
- Apply feature engineering techniques
- Build a predictive model using Linear Regression
- Evaluate the model using standard performance metrics

PROBLEM STATEMENT

To develop a machine learning model that accurately predicts gold prices based on historical data and relevant features using Linear Regression.

The main objectives of this project are:

- To build a predictive model for gold prices
- To achieve high prediction accuracy (low error rate)
- To analyze feature importance affecting gold price
- To evaluate model performance using metrics such as:
    - MAPE
    - R^2 Score
    - MAE
    - RMSE

Expected Outcome:

- A reliable regression model with high accuracy (achieved: $\mathbf{R^2 = 0.9515}$)
- Insights into factors influencing gold prices

THEORETICAL BACKGROUND

1. Linear Regression Theory

Linear Regression models the relationship between variables using the equation:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_n x_n$$

Where:

- y = predicted gold price
- $x_1, x_2, \cdots$ = input features
- β_0 = intercept
- β_i = coefficients
- ϵ = error term

The objective is to minimize the error using **Least Squares Method**:

$$\text{Error} = \sum (y_i - \hat{y}_i)^2$$

2. Loss Function (Least Squares Method)

The model minimizes the error using Mean Squared Error:

$$MSE = \frac{1}{n} \sum_{i=1}^{n} (y_i - \hat{y}_i)^2$$

3. Evaluation Metrics

- **MAPE (Mean Absolute Percentage Error)**

$$MAPE = \frac{1}{n} \sum \left| \frac{y - \hat{y}}{y} \right| \times 100$$

- **R^2 Score**

$$R^2 = 1 - \frac{SS_{res}}{SS_{tot}}$$

- **MAE (Mean Absolute Error)**

$$MAE = \frac{1}{n} \sum |y - \hat{y}|$$

- **RMSE (Root Mean Squared Error)**

$$RMSE = \sqrt{MSE}$$

4. Literature Survey

Various techniques have been used for gold price prediction:

Algorithm	Description
Linear Regression	Simple and interpretable
ARIMA	Time-series forecasting
LSTM	Deep learning for sequential data
Random Forest	Handles non-linearity

5. Justification for Choosing Linear Regression

- Easy to implement and interpret
- Works well for structured tabular data
- Computationally efficient
- Provides feature importance through coefficients
- Achieved high accuracy (**R^2 = 0.95**) in this project

ALGORITHM EXPLANATION WITH EXAMPLE

Step by step process:

1. Load dataset
2. Clean numerical values
3. Feature Engineering:
    - Lag features (lag_1, lag_3, etc.)
    - Rolling averages
    - Volatility (high-low range)
4. Scale data using MinMaxScaler
5. Split dataset (80% train, 20% test)
6. Train Linear Regression model
7. Predict values
8. Evaluate model

Example :

Step 1 : Sample dataset

Date	Price	Open	High	Low
2013-01-02	1689.9	1675.8	1695.0	1672.1
2013-01-03	1675.6	1688.0	1689.3	1664.3
2013-01-04	1649.9	1664.4	1664.4	1630.0

Step 2 : Feature Engineering

From the data , we create new features.

Price	lag_1	lag_3	roll_mean_7	day_of_week
1649.9	1675.6	1689.9	~1671.8	4

Explanation:

- **lag_1** → Previous day's price
- **lag_3** → Price 3 days ago
- **roll_mean_7** → Average of last 7 days
- **day_of_week** → Numerical value (0–6)

Step 3: Model Input

The model takes:

$$X = [lag_1, lag_3, roll_mean_7, ..., month, year]$$

Example input:

$$X = [1675.6, 1689.9, 1671.8, 4, 1, 2013]$$

Step 4: Prediction using Linear Regression

The model predicts price using learned coefficients:

$$Price = \beta_0 + \beta_1(lag_1) + \beta_2(lag_3) + \beta_3(roll_mean_7) + ...$$

Step 5: Example Prediction

Assume:

- Actual Price = **1650**
- Predicted Price = **1642**

Error:

$$Error = Actual - Predicted = 1650 - 1642 = 8$$

Step 6: Interpretation

- Small error → Good prediction
- Model learns patterns from past prices
- Rolling mean and lag features improve accuracy

IMPLEMENTATION CODE AND DATASET USED

Dataset Details :

Category	Description / Example
Dataset Name	Gold Price (2013–2023)
Domain	Finance
Objective	Regression
Data Source	Public dataset
Number of Samples	2548 (after preprocessing)
Data Type	Tabular
Instance Description	Daily gold price data
Features (Inputs)	Open, High, Low, Lag values, Rolling stats
Feature Types	Numerical
Target Variable	Price
Number of Classes	Not applicable
License	Public
Version	1.0

PYTHON CODE:

```
"""
Gold Price Prediction — Linear Regression
Dataset : Gold Price (2013-2023).csv
Results : MAPE ~0.67%  |  R² ~0.95  |  MAE ~$12  |  RMSE ~$16

Plot saved → C:\Gold price prediction using Linear Regression\gold_price_prediction.png
```

Output Explanation

- Very low MAPE → highly accurate predictions
- High R^2 → model explains ~95% variance
- Low MAE & RMSE → minimal prediction error

Feature Importance

Top influencing features:

1. roll_mean_7
2. lag_1
3. lag_3
4. lag_7

Visualization :

- Actual vs Predicted line graph
- Residual error plot
- Feature importance chart
- Scatter plot (Actual vs Predicted)

These confirm:

- Strong model performance
- Minimal bias
- Good generalization

Figure: Visualization of Gold Price Prediction Results using Linear Regression

Description : The figure presents multiple visualizations of the Linear Regression model performance. The **Actual vs Predicted graph** shows that predicted values closely follow the real gold prices. The **residual plot** indicates that errors are mostly centered around zero, suggesting minimal bias. The **feature importance chart** highlights key influencing factors such as *roll_mean_7* and *lag_1*. The **scatter plot** demonstrates a strong linear relationship between actual and predicted values, confirming high model accuracy and good generalization.

RESULTS AND FUTURE ENHANCEMENT

The project successfully developed a high-accuracy gold price prediction model using Linear Regression. The model achieved strong performance metrics, demonstrating its ability to accurately capture the relationship between historical data and future price trends. Additionally, key features such as rolling averages and lag values were identified as major factors influencing gold prices, providing valuable insights into the underlying patterns.

When compared with other methods, Linear Regression offers a good balance between accuracy and simplicity. While models like LSTM have the potential to achieve higher accuracy due to their ability to capture complex time-series patterns, they come with higher computational complexity. Similarly, Random Forest models provide medium to high accuracy but are more complex than Linear Regression. In contrast, Linear Regression remains efficient and interpretable, making it suitable for this project.

For future enhancements, the model can be improved by incorporating advanced techniques such as LSTM for better time-series forecasting. Including additional external factors like inflation rate, USD index, and oil prices can further enhance prediction accuracy. Moreover, applying hyperparameter tuning and developing a real-time prediction system would make the model more robust and practical for real-world applications.
